Histomorphometric Changes in the Testes and Epididymis of Wistar Strain Albino Rats Following Fourteen Days Oral Administration of Therapeutic Doses of Some Antibiotics

Cambios Histomorfométricos en los Testículos y el Epidídimo de Ratas Cepa Wistar Albinas Después de Catorce Días de Administración Oral de Dosis Terapéuticas de Algunos Antibióticos

*Awobajo, F. O.; **Raji, Y. & ***Akinloye, A. K.

SUMMARY: Studies on testes and epididymis tissue of rats treated orally for fourteen days with therapeutic doses of cloxacillin (6mg/100g/day), ampicillin (4mg/100/day) and tetracycline (12mg/100g/day) separately showed a significant reduction in testicular and epididymis architecture. Microscopic studies of these male reproductive organs further revealed a significant alteration in the epididymis as revealed by a significant reduction (p<0.05) in epididymal ductular diameter (EDD), and epididymal epithelial height (EEH) in treated group of animals. A significant increase (p<0.05) was however recorded in epididymal luminal diameter (ELD) in all the animals after the two and three week’s recovery period allowed. This gives another insight into the toxicity activities of these antibiotics on male reproductive organs, apart from reduction in serum testosterone level, decreased sperm motility, decreased spermatozoa count and decrease in RNA and DNA content of spermatogenic cells as earlier reported.

KEY WORDS: Antibiotics; Testes; Epididymis; Histomorphometry.

INTRODUCTION

The reversible anti-fertility effects of many antibiotics on male reproduction have been well documented (Shlegel *et al*., 1991). These adverse effects have been shown on such parameters as serum hormonal level, reproductive organ weight, physical and chemical qualities of semen sample as well as spermatozoa quality, quantity and motility in the semen sample (Raji *et al*., 2006). There is however, scanty information on the testicular architectural assessment using histomorphometric analysis of antibiotics on testicular and epidydimal histology (Aumüller *et al*., 1985).

The use of histopathological evaluations, while evaluating animal tissue is of prominent role in male reproductive risk assessment. Organs that are often evaluated include the testes, epididymis, prostate, seminal vesicles, and pituitary. Histological evaluations are especially useful in providing a relatively sensitive indicator of damage; and with short-term dosing, providing information on target cells, extent of toxicity, and, indicating the potential for recovery. High quality information can be obtained on spermatogenesis from an adequately prepared testicular tissue (Russell *et al*., 1990; Hess & Moore, 1993). The basic morphology of other male reproductive organs like the epididymis, and accessory sex glands have been described as well as the histopathologic alterations that may accompany certain disease states (Fawcett, 1986; Akinloye *et al*., 2002). Although, there is extensive documentation on effect of exposure to the toxic activities of antibiotics on spermatogenesis and spermatozoa morphology (Shlegel *et al*.), less is known about structural changes in the testis and epididymis themselves. With the epididymis and accessory sex glands, histologic evaluation is usually limited to the height and possibly the integrity of the secretory epithelium.
In this research work, we use stereological analysis of the testicular and epididymal tissues to assess infertility in rats treated with the following antibiotics; Ampicillin, (4mg/100g b.w./day) Cloxacillin (6 mg/100g b.w./day), Tetracycline (12mg/100g b.w./day), and their corresponding one and two weeks recovery groups.

MATERIAL AND METHOD

Animals and Treatment. Matured male Wistar albino rats (130-150grams) were used for this experimental study. There were ten (10) groups of eight animals each. They were provided with rat pellet and water ad libitum throughout the period of the experiment. The treated groups are as follows: Ampicillin treated group, AT, (4mg/100g b. w./day); Cloxacillin treated group, CT, (6mg/100g b. w./day); and Tetracycline treated group, TT, (12mg/100g b. w./day). All the doses used were therapeutic doses calculated for the weight of the rats. The control group (C) received the same volume of the vehicle (distilled water) alone. The drugs were administered orally using separate sterilized oral dosing needle for a period of fourteen days. There were also two recovery groups of two and three weeks for each of the test or treated groups. The recovery groups were also treated with the antibiotics as their corresponding test groups after which they were allowed a recovery period ranging from two to three weeks respectively.

Body and Organ Weight. The initial body weight (IBW), weight during the experiment (WDE) and final body weight (FBW) of the animals were recorded for each group during the experimental period allowed. Rats were sacrificed by an overdose of pentobarbitone sodium (45mg/kg body weight ip, Sigma, USA) on the last day of the experiment. The animal abdomen was opened up and the prostate gland (PGW), testis (TW) and epididymis (EW) carefully dissected out. The fats are trimed of the organs and the wet weights measured using an electronic analytical balance (model WH200-4, by Hauser).

Histomorphometric Study. The tissues of the testes and epididymis were fixed in fresh Bouin’s fluid and embedded in paraffin wax. Section of 5 µm thick were cut and stained in haematoxylin and eosin. The testes histopathology was performed according to Sobarzo & Bustos-Obregon (Cited by Bustos-Obregon & Gonzalez-Hormazabal, 2003). The tissue sections were observed under a light microscope (x400 objective) for histomorphometric changes according to Akinloye et al. and Glander (1984). The seminiferous tubular diameter (STD), epididymal epithelial height (EEH), epididymal ductular diameter (EDD), epididymal luminal diameter (ELD) of 50 cross sections per animal were measured, using calibrated eye-piece micrometer (Graticules Ltd. Toubridge Kent).

Statistical Analysis. Results were expressed as Mean±SEM and analyzed using ANOVA. The test of significance was placed at p<0.05. Bar charts were also used for graphical representation.

RESULTS

Body and Organ Weight. In all the treated groups and the counterpart recovery, the body weight was not significantly different from the control group (Table I). The relative weight (in percentage) of the testis were significantly decreased (P<0.05) in cloxacillin treated group and the cloxacillin recovery group only. The cloxacillin and tetracycline treated groups and their respective recovery groups exhibited a significant decrease (P<0.05) in the epididymal weights.

Final body weight in grams (FBW). Testicular weight (TW) and Epididymis weight (EW) presented as percentage relative organ weight in gram %. ATR: Ampicillin Treated Recovery, CTR: Cloxacillin Treated Recovery, and TTR: Tetracycline Treated Recovery.

Number of animals = 8 rats per group. * Significantly different from normal control (P<0.05). † Significantly different from corresponding treated group (P<0.05)
Histomorphometric findings. The general conditions of the animals in all the groups before and after treatment were good. The treated groups showed significant and meaningful histopathological damage compared with control. This is evidenced by the presence of moderate to severe testicular degeneration, necrosis and sloughing of germinal layers accompanied with vascular congestion and interstitial oedema. The presence of large number of foaming macrophages in all the recovery groups, especially the two weeks recovery group gave evidence in support of repair and regeneration of new cells, while clearing off the old cell debris (Fig. 5a-5d).

Arrows showing intact lumen of seminiferous tubule (arrow A), intact basement membrane and sertoli cells (arrow B), intact interstitial tissue (arrow C), cells of Leydig, and peritubular capillaries and venules. (H & E stain.).

Fig. 5b. Light micrograph of the testicular tissue in rat administered therapeutic dose of ampicillin orally for 2 weeks, with arrows showing slight seminiferous tubular degeneration (arrow A) with scattered areas of interstitial edema (C). There was also necrosis of the sertoli cell responsible for supporting developing spermatocytes (arrow B). (H & E stain.).

Fig. 5c. Light micrograph of the testicular tissue in rat administered therapeutic dose of cloxacillin orally for 2 weeks treated with arrows showing moderate (arrow A & B) to severe degeneration of the seminiferous tubules and shrinkage (arrow C). (H & E stain.).

Fig. 5e. Light micrograph of epididymal tissue from the Control rat with arrow showing the epididymal luminal diameter (A), epididymal epithelia height (B), and epidyidal ductular diameter (C). (H & E stain.).
DISCUSSION

Histopathology evaluations of test animal tissues is been said to have a prominent role in male reproductive risk assessment. It provides information on the severity of the toxicity and cellular site of the damage as well as the possible potential for recovery (USEPA, 1996). The results of the wet organ weight from rats treated orally with the therapeutic doses of the ampicillin, cloxacillin, and tetracycline for fourteen days showed that there significant (P<0.05) reduction in testicular and epididymal weight. The observed degenerative changes were associated with significant reduction in testicular and epididymal weight. This is in agreement with previous findings of the testosterone level in animals treated with these antibiotics (Awobayo et al.).

However, these negative effects vis a vis testicular morphological disruption appear to be reversible after the withdrawal of the treatment as regeneration changes both in term of the histomorphometry of the tissue as well as by the increase in the concentration of the macrophages that are known for clearing of cellular debris during tissue repair (Leor et al., 2006). A significant increase (p<0.05) was recorded in epididymal lumina diameter (ELD) in all the animals after the two and three week’s recovery period allowed.

This work suggests that long-term use of these antibiotics even at therapeutic doses (or their abuse) could produce a deleterious effect on testicular histomorphology leading to reduced fertility. Also, the testicular histomorphometry atrophy recorded in animals treated with the antibiotics studied may provide explanation for the reduction in serum testosterone level earlier reported (Awobayo et al.) as leydig cells are responsible for the synthesis of testosterone.
